TOPIC 5

MODELLING ASSET RETURN VOLATILITY

程序代写代做 CS编程辅导

1. Introduction

We introd CH class of models which were developed to account for the pe returns which, as we have seen, is a typical feature of asset return dat H refer, respectively, to an Autoregressive Conditional Hete eralized Autoregressive Conditional Heteroscedastic are heteroscedatic and autoregressive because they model time-varyi s and do that by taking account of past volatility.

2. ARCH Processes

Consider a very simple model for returns $\{y_t\}$, which in practice is not an unreasonable characterization for mean returns, namely,

WeChat: cstutorcs

$$y_t = c + \varepsilon_t \tag{1}$$

Assignment Project Exam Help

where $\varepsilon_t \sim WN(0,\sigma^2)$ and c is the intercept. This assumption means that the unconditional mean and variance of the innovation ε_t are constant and finite (equal to zero and σ^2, respectively) and that the innovations are serially uncorrelated at all leads and lags. In topic 3, we made the further assumption that the innovations were independently and identically distributed so that the innovations were characterized as a strict white noise process, that is, $\varepsilon_t \sim iid\,WN(0,\sigma^2)$. The assumption of independence means that the conditional probability density function of $\varepsilon_t \mid \Omega_{t-1}$ where $\Omega_{t-1} = \{\varepsilon_{t-1}, \varepsilon_{t-2}, \ldots\}$ is the same as the unconditional probability density function of ε_t. This has the implication that the conditional variance of the innovation, namely, $\mathrm{var}(\varepsilon_{t+j} \mid \Omega_t)$ depends only on j and not on the conditioning information set Ω_t. Thus, for example, when j=1

Email: tutorcs@163.com

QQ: 749389476

$$\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) = \mathrm{var}(\varepsilon_{t+1} \mid \Omega_t)$$

https://tutorcs.com

The arrival of "news" at t, namely ε_t, does not affect the value of conditional variance of the innovation one period ahead, namely, at t+1. In other words, the conditional variance does not adapt to the arrival of new conditioning information. In financial markets, however, return volatility responds to the arrival of "news" and the present specification cannot capture this feature of financial data.

To do so, we will continue to assume that the innovations are white noise but that they are *not* strictly white noise by dropping the assumption of independence. In particular, we will assume a particular dependence structure in the conditional variance of the innovation.

The Autoregressive Conditional Heteroscedastic Model of order one (ARCH(1)) for the innovation ε_t is

$$\varepsilon_t \mid \Omega_{t-1} \sim N(0, \sigma_t^2)$$
$$\sigma_t^2 = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 \qquad \alpha_0 > 0,\ 0 \le \alpha_1 < 1 \tag{2}$$

程序代写代做 CS编程辅导

where $\sigma_t^2 = \mathrm{var}($ [illegible] onal variance of ε_t based on the information set $\Omega_{t-1} = \{\varepsilon_{t-1}, \varepsilon_{t-2},$ [illegible] ially uncorrelated but they are not serially independent beca [illegible] ional variance of ε_t depends on the one period lagged value of ε [illegible] stribution is assumed normal so that equations (1) and (2) can be est [illegible] ximum likelihood estimation.

It is impo [illegible] is a weak white noise process and is covariance stationary. The u [illegible] d the unconditional variance of ε are constant and finite and are, respectively,

$$E(\varepsilon_t) = 0$$
$$\mathrm{var}(\varepsilon_t) = E(\varepsilon_t - E(\varepsilon_t))^2 = \frac{\alpha_0}{1-\alpha_1}$$

WeChat: cstutorcs
Assignment Project Exam Help

The restrictions $\alpha_0 > 0,\ \ 0 \le \alpha_1 < 1$, ensure that the unconditional variance is positive and finite and, also, that the conditional variance is always positive. The important point is that the unconditional mean and variance are finite and constant as required for covariance stationarity. Also, as stated earlier the ε_t's are serially uncorrelated. The conditional mean and variance are

Email: tutorcs@163.com
QQ: 749389476
https://tutorcs.com

$$E(\varepsilon_t \mid \Omega_{t-1}) = 0$$
$$\begin{aligned}\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) &= E[(\varepsilon_t - E(\varepsilon_t \mid \Omega_{t-1}))^2 \mid \Omega_{t-1}] \\ &= E(\varepsilon_t^2 \mid \Omega_{t-1}) \\ &= \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 \\ &= \sigma_t^2\end{aligned}$$

The important point here is that the conditional variance is time-varying and thus heteroscedastic. Note that

$$\mathrm{var}(\varepsilon_{t+1} \mid \Omega_t) = \alpha_0 + \alpha_1 \varepsilon_t^2$$

and it follows that $\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) \ne \mathrm{var}(\varepsilon_{t+1} \mid \Omega_t)$. The arrival of news, namely, ε_t, will affect the conditional variance for next period (at time t+1). This is the key feature of ARCH type models: the conditional variance adapts to the conditioning information set. Clearly, if $\alpha_1 = 0$, there are no conditional variance dynamics and we are back to case of independence where $\varepsilon_t \sim iidWN(0, \alpha_0)$ from which it follows, for example, that $\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) = \mathrm{var}(\varepsilon_{t+1} \mid \Omega_t)$.

The ARCH model is capable of capturing the feature of volatility clustering that is observed in financial data where large changes in returns tend to be followed by large changes, and small changes in returns by small changes, of either sign. A large observed ε_{t-1}^2 produces a large conditional variance at time *t*, that is, a large σ_t^2, thereby increasing the likelihood of a [illegible] ARCH process models conditional variance dynamics in an au[illegible]

Clearly, in [illegible] (1), the unconditional and conditional mean of y_t is just c. The con[illegible] y_t is time-varying and equal to:

$$\begin{aligned}
\mathrm{var}(y_t \mid \Omega_{t-1}) &= E[(y_t - E(y_t \mid \Omega_{t-1}))^2 \mid \Omega_{t-1}] \\
&= E(c + \varepsilon_t - c)^2 \mid \Omega_{t-1}) \\
&= E(\varepsilon_t^2 \mid \Omega_{t-1}) \\
&= \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 \\
&= \sigma_t^2
\end{aligned}$$

Equation (1) is referred to as the mean equation and equation (2) as the variance equation. In practice, both equations are estimated jointly using maximum likelihood techniques and an estimate is obtained for each parameter, namely, for c, α_0 and α_1. There is no need for the mean equation to take the particularly simple form of equation (1). The mean equation could easy be:

$$y_t = \beta_0 + \beta_1 X_{1,t} + \beta_2 X_{2,t} + \varepsilon_t \quad \text{with } E(\varepsilon_t \mid X_{1,t}, X_{2,t}) = 0$$

or

$$y_t = c + \varepsilon_t + \theta \varepsilon_{t-1}$$

or

$$y_t = c + \rho y_{t-1} + \varepsilon_t$$

where, in each case, $\varepsilon_t \sim WN(0, \sigma^2)$. Similarly, there is no need to restrict the variance equation to an ARCH specification with one autoregressive lag. The ARCH(q) specification for the variance equation is:

$$\begin{aligned}
&\varepsilon_t \mid \Omega_{t-1} \sim N(0, \sigma_t^2) \\
&\sigma_t^2 = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \alpha_2 \varepsilon_{t-2}^2 + \ldots + \alpha_q \varepsilon_{t-q}^2 \\
&\alpha_0 > 0, \ \alpha_i \geq 0 \ \text{ for all } i = 1 \ to \ q, \ \sum_{i=1}^{q} \alpha_i < 1
\end{aligned}$$

程序代写代做CS编程辅导
WeChat: cstutorcs
Assignment Project Exam Help
Email: tutorcs@163.com
QQ: 749389476
https://tutorcs.com

The stated restrictions are sufficient to ensure that the conditional and unconditional variances are positive and finite and that ε_t is covariance stationary. Note that for the ARCH(q) process, the unconditional mean, variance and covariance are,

程序代写代做 CS编程辅导

$$E(\varepsilon_t) = 0$$

$$\mathrm{var}(\varepsilon_t) =$$

$$\mathrm{cov}(\varepsilon_t, \varepsilon_{t-}$$

while the conditi ce are,

$$E(\varepsilon_t \mid \Omega_{t-1}) = 0$$

$$\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \alpha_2 \varepsilon_{t-2}^2 + \ldots + \alpha_q \varepsilon_{t-q}^2$$

$$= \sigma_t^2$$

WeChat: cstutorcs

Consider now the y_t process. It is important to realize that no matter the specific form of the mean equation for y_t, it will always be the case that

Assignment Project Exam Help

$$\mathrm{var}(y_t \mid \Omega_{t-1}) = \mathrm{var}(\varepsilon_t \mid \Omega_{t-1})$$

$$= \sigma_t^2$$

Email: tutorcs@163.com

For example, suppose y_t follows the AR(1) process given above. Then the conditional mean of y_t is

QQ: 749389476

$$E(y_t \mid \Omega_{t-1}) = E[(c + \rho y_{t-1} + \varepsilon_t) \mid \Omega_{t-1}]$$

https://tutorcs.com

$$= c + \rho y_{t-1} + E(\varepsilon_t \mid \Omega_{t-1})$$

$$= c + \rho y_{t-1}$$

which is the forecast value of y_t on the basis of time *t*-1 information.
Now

$$\mathrm{var}(y_t \mid \Omega_{t-1}) = E[(y_t - E(y_t \mid \Omega_{t-1}))^2 \mid \Omega_{t-1}]$$

$$= E[(c + \rho y_{t-1} + \varepsilon_t - (c + \rho y_{t-1}))^2 \mid \Omega_{t-1}]$$

$$= E[\varepsilon_t^2 \mid \Omega_{t-1}]$$

$$= \sigma_t^2$$

The two-standard error confidence interval for the one-step ahead forecast of y_t, based on information available at time *t*-1 (i.e. Ω_{t-1}) for the AR(1) model is:

$$c + \rho y_{t-1} \pm 2\sqrt{\sigma_t^2}$$

程序代写代做 CS编程辅导

In the case of an ARCH(1) process it is

$$c + \rho y_{t-1}$$

On the basis of ti two-standard error confidence interval for the one-step ahead foreca formation available at time t (i.e. Ω_t) is:

$$c + \rho y_t \pm 2\sqrt{\sigma_{t+1}^2}$$

In the case of an ARCH(1) process it is

WeChat: cstutorcs

$$c + \rho y_t \pm 2\sqrt{\alpha_0 + \alpha_1 \varepsilon_t^2}$$

Assignment Project Exam Help

Notice that not only is the forecasted value of y updated, as it now depends on y_t, but also the standard error of the forecast is updated as it depends on ε_t^2. Thus, the arrival of new information at time t influences not only the forecast but the confidence interval associated with the forecast.

Email: tutorcs@163.com

2. GARCH Processes

QQ: 749389476

The generalized ARCH or GARCH(1,1) model is:

$$y_t = c + \varepsilon_t \tag{3}$$

$$\varepsilon_t \mid \Omega_{t-1} \sim N(0, \sigma_t^2)$$

https://tutorcs.com

$$\sigma_t^2 = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \beta_1 \sigma_{t-1}^2 \tag{4}$$

$$\alpha_0 > 0,\ \ \alpha_1 \geq 0,\ \ \beta_1 \geq 0,\ \ \alpha_1 + \beta_1 < 1$$

Here the conditional variance at time t (σ_t^2) depends not only on last period's squared innovation (ε_{t-1}^2) but also on the conditional variance last period (σ_{t-1}^2). The parameter restrictions ensure that the unconditional variance and the conditional variance are positive and finite and that y_t is covariance stationary. Equation (3) is the mean equation. In this case, it is very simple but it can assume any form, for example, a regression equation or an MA or AR process. Equation (4) is the variance equation. The unconditional mean and the unconditional variance of ε are constant and finite and are, respectively,

$$E(\varepsilon_t) = 0$$

程序代写代做 CS编程辅导

$$\mathrm{var}(\varepsilon_t) = E(\varepsilon_t - E(\varepsilon_t))^2 = \frac{\alpha_0}{1 - \alpha_1 - \beta_1}$$

Note that the unc[illegible] is $\mathrm{cov}(\varepsilon_t, \varepsilon_{t-j}) = 0$ for j>0. The conditional mean and variance are

$$E(\varepsilon_t \mid \Omega_{t-}[illegible]$$

$$\mathrm{var}(\varepsilon_t \mid \Omega[illegible]\Omega_{t-1}))^2 \mid \Omega_{t-1}]$$

$$= E(\varepsilon_t^2 \mid \Omega_{t-1})$$

$$= \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \beta_1 \sigma_{t-1}^2$$

$$= \sigma_t^2$$

WeChat: cstutorcs

The important point is that the unconditional variance is constant, as must be the case under covariance stationarity, whereas the conditional variance is time-varying.

Assignment Project Exam Help

The two-standard error confidence interval for the one-step ahead forecast of y_t, based on information available at time t-1 (i.e. Ω_{t-1}) for the AR(1) model is:

Email: tutorcs@163.com

$$c + \rho y_{t-1} \pm 2\sqrt{\sigma_t^2}$$

In the case of a GARCH(1,1) process it is

QQ: 749389476

$$c + \rho y_{t-1} \pm 2\sqrt{\alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \beta_1 \sigma_{t-1}^2}$$

https://tutorcs.com

On the basis of time t information, the two-standard error confidence interval for the one-step ahead forecast of y_t, based on information available at time t (i.e. Ω_t) is:

$$c + \rho y_t \pm 2\sqrt{\sigma_{t+1}^2}$$

In the case of an GARCH(1,1) process it is

$$c + \rho y_t \pm 2\sqrt{\alpha_0 + \alpha_1 \varepsilon_t^2 + \beta_1 \sigma_t^2}$$

Notice that not only is the forecasted value of y updated, as it now depends on y_t, but also the standard error of the forecast is updated as it depends on ε_t^2 and σ_t^2. Thus, the arrival of new information at time t influences not only the forecast but the confidence interval associated with the forecast.

In practice, it was found that to adequately model volatility, the ARCH(q) specification required a very long number of lags, that is, q was found to be very large. Not only do a large number of lags use up degrees of freedom but with so many

parameters to estimate it is more probable that one or more of the estimated parameters may be negative, violating the sign restrictions on the parameters. This leads to the development of the GARCH model. We will now show that the GARCH(1,1) model is equivalent to a restricted ARCH model of infinite order. Now

程序代写代做 CS编程辅导

$$\sigma_t^2 = \alpha_0 +$$

Substitute for σ_{t-}^2

$$\sigma_t^2 = \alpha_0 + \quad {}^2_{t-2} + \beta_1\sigma_{t-2}^2)$$

$$= \alpha_0(1+\beta_1) + \alpha_1(\varepsilon_{t-1} + \beta_1\varepsilon_{t-2}^2) + \beta_1^2\sigma_{t-2}^2$$

Continue in this way to get,

WeChat: cstutorcs

$$\sigma_t^2 = \alpha_0(1+\beta_1+\ldots+\beta_1^{j-1}) + \alpha_1(\varepsilon_{t-1}^2 + \beta_1\varepsilon_{t-2}^2 + \ldots + \beta_1^{j-1}\varepsilon_{t-j}^2) + \beta_1^j\sigma_{t-j}^2$$

As $j \to \infty$,

Assignment Project Exam Help

$$\sigma_t^2 = \frac{\alpha_0}{1-\beta_1} + \alpha_1(\varepsilon_{t-1}^2 + \beta_1\varepsilon_{t-2}^2 + \ldots + \beta_1^{j-1}\varepsilon_{t-j}^2 + \ldots)$$

Email: tutorcs@163.com

This follows because $\beta_1 < 1$, given the sign restrictions of the GARCH(1,1) model. Thus, the GARCH(1,1) model is equivalent to an ARCH(∞) where the coefficients on the lagged squared innovations decline geometrically. The GARCH(1,1) is a parsimonious model since there are only three parameters to estimate: $\alpha_0, \alpha_1, \beta_1$.

QQ: 749389476

In many finance applications, particularly in Value-at-Risk calculations and the pricing of options, forecasts of the conditional variance are required. We will now derive an expression for the *h*-step ahead forecast of the conditional variance for the GARCH(1,1) specification. By definition

https://tutorcs.com

$$\sigma_t^2 = E(\varepsilon_t^2 \mid \Omega_{t-1})$$

Updating by *h* periods, we obtain

$$\sigma_{t+h}^2 = E(\varepsilon_{t+h}^2 \mid \Omega_{t+h-1})$$

The optimal forecast of σ_{t+h}^2 based on information available at time *t* is $E(\sigma_{t+h}^2 \mid \Omega_t)$. By construction,

$$E[\sigma_{t+h}^2 \mid \Omega_t] = E[E(\varepsilon_{t+h}^2 \mid \Omega_{t+h-1}) \mid \Omega_t]$$
$$= E(\varepsilon_{t+h}^2 \mid \Omega_t) \qquad (5)$$

where the last equality follows from the law of iterative expectations. The GARCH(1,1) model is

程序代写代做 CS编程辅导

$$\sigma_{t+h}^2 = \alpha_0 + \alpha_1 \varepsilon_{t+h-1}^2 + \beta_1 \sigma_{t+h-1}^2$$

Take the conditio[illegible]e basis of the information set Ω_t to get

$$E(\sigma_{t+h}^2 \mid \Omega[illegible] \mid \Omega_t) + \beta_1 E(\sigma_{t+h-1}^2 \mid \Omega_t)$$

$$[illegible](\sigma_{t+h-1}^2 \mid \Omega_t) \qquad (6)$$

where the last equality follows from equation (5). By recursive substitution, we can write equation (6) as

WeChat: cstutorcs

$$E(\sigma_{t+h}^2 \mid \Omega_t) = \alpha_0[1 + (\alpha_1 + \beta_1) + (\alpha_1 + \beta_1)^2 + \ldots + (\alpha_1 + \beta_1)^{h-2}] + (\alpha_1 + \beta_1)^{h-1} E(\sigma_{t+1}^2 \mid \Omega_t)$$

$$= \alpha_0[1 + (\alpha_1 + \beta_1) + (\alpha_1 + \beta_1)^2 + \ldots + (\alpha_1 + \beta_1)^{h-2}] + (\alpha_1 + \beta_1)^{h-1} \sigma_{t+1}^2$$

Assignment Project Exam Help

where the last step follows because σ_{t+1}^2 is known at time t. This formula can also be used to calculate a two standard error confidence band around the optimal h-step ahead forecast of y. Fortunately, EViews automatically calculates forecasts of the h-step ahead conditional variance using this formula for the case of a GARCH(1,1) process. Provided $\alpha_1 + \beta_1 < 1$, the forecast of the conditional variance will converge to the unconditional variance of ε_t as $h \to \infty$. That is

Email: tutorcs@163.com

QQ: 749389476

$$\lim_{h \to \infty} E(\sigma_{t+h}^2 \mid \Omega_t) = \frac{\alpha_0}{1 - (\alpha_1 + \beta_1)} = \mathrm{var}(\varepsilon_t)$$

https://tutorcs.com

Further if ε_t follows a GARCH(1,1) process, then it can be shown that ε_t^2 has an ARMA(1,1) representation, namely,

$$\varepsilon_t^2 = \alpha_0 + (\alpha_1 + \beta_1)\varepsilon_{t-1}^2 - \beta_1 v_{t-1} + v_t$$

where $v_t = \varepsilon_t^2 - \sigma_t^2$ is the difference between the squared innovation and the conditional variance at time t. (You will be asked to show this result in a tutorial exercise). The term ε_t^2 is a noisy proxy for the conditional variance σ_t^2: ε_t^2 is an unbiased predictor of σ_t^2 but it is more volatile. Also, recall that real world financial asset returns are typically unconditionally symmetric but leptokurtic (that is, more peaked in the centre and with fatter tails than a normal distribution). It turns out that the implied unconditional distribution of the conditionally normal GARCH process is also symmetric and leptokurtic.

Finally, the GARCH(1,1) can be extended to a GARCH(p,q) process given by

$$\varepsilon_t \mid \Omega_{t-1} \sim N(0, \sigma_t^2)$$

程序代写代做 CS编程辅导

$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i \varepsilon_{t-i}^2 + \sum_{i=1}^{p} \beta_i \sigma_{t-i}^2$$

$$\alpha_0 > 0, \alpha_i \quad \sum_{i=1}^{p} \beta_i < 1$$

As before, the sta that ε_t is covariance stationary and that the conditional variar nconditional mean and the unconditional variance of ε are constant spectively,

$$E(\varepsilon_t) = 0$$

$$\mathrm{var}(\varepsilon_t) = E(\varepsilon_t - E(\varepsilon_t))^2 = \frac{\alpha_0}{1 - \sum_{i=1}^{q} \alpha_i - \sum_{i=1}^{p} \beta_i}$$

WeChat: cstutorcs

The conditional mean and variance are

Assignment Project Exam Help

$$E(\varepsilon_t \mid \Omega_{t-1}) = 0$$

$$\mathrm{var}(\varepsilon_t \mid \Omega_{t-1}) = E[(\varepsilon_t - E(\varepsilon_t \mid \Omega_{t-1}))^2 \mid \Omega_{t-1}]$$

Email: tutorcs@163.com

$$= E(\varepsilon_t^2 \mid \Omega_{t-1})$$

$$= \alpha_0 + \sum_{i=1}^{q} \alpha_i \varepsilon_{t-i}^2 + \sum_{i=1}^{p} \beta_i \sigma_{t-i}^2$$

QQ: 749389476

$$= \sigma_t^2$$

Also, as before, no matter the specific form of the mean equation for y_t, it will always be the case that

https://tutorcs.com

$$\mathrm{var}(y_t \mid \Omega_{t-1}) = \mathrm{var}(\varepsilon_t \mid \Omega_{t-1})$$

$$= \sigma_t^2$$

3. Maximum Likelihood Estimation of the GARCH(1,1) Process

In lecture note 2, we discussed maximum likelihood estimation of the simple linear regression model

$$Y_t = \beta_0 + \beta_1 X_t + u_t \text{ where } u_t \sim iid\, N(0, \sigma^2).$$

The log-likelihood function for this model is

$$l(\beta_0, \beta_1, \sigma^2 \mid Y_t, X_t \;\; t = 1, \ldots, T) = -\frac{T}{2}\ln(2\pi) - \frac{T}{2}\ln\sigma^2 - \frac{1}{2\sigma^2}\sum_{t=1}^{T}(Y_t - \beta_0 - \beta_1 X_t)^2$$

Now lets assume the conditional mean equation is

程序代写代做 CS编程辅导

$$Y_t = \delta_0 + \delta_1 X_t + \varepsilon_t$$

and the condition s

$$\varepsilon_t \mid \Omega_{t-1} \sim$$

$$\sigma_t^2 = \alpha_0 +$$

$$\alpha_0 > 0, \quad c \qquad \beta_1 < 1$$

The log-likelihood function for this model is

$$l(\delta_0, \delta_1, \alpha_0, \alpha_1, \beta_1)$$

WeChat: cstutorcs

$$= -\frac{T}{2}\ln(2\pi) - \frac{1}{2}\sum_{t=1}^{T}\ln(\alpha_0 + \alpha_1\varepsilon_{t-1}^2 + \beta_1\sigma_{t-1}^2) - \frac{1}{2}\sum_{t=1}^{T}\frac{(Y_t - \delta_0 - \delta_1 X_t)^2}{(\alpha_0 + \alpha_1\varepsilon_{t-1}^2 + \beta_1\sigma_{t-1}^2)}$$

Assignment Project Exam Help

Once we substitute $\varepsilon_{t-1}^2 = (Y_{t-1} - \delta_0 - \delta_1 X_{t-1})^2$ and σ_{t-1}^2 in the log-likelihood function, it is then possible to maximize the log-likelihood with respect to each of the parameters ($\delta_0, \delta_1, \alpha_0, \alpha_1, \beta_1$). The values of ε_0^2 and σ_0^2 have to be set and they are usually set equal to the unconditional variance of the $\varepsilon's$ from the estimated mean equation, which is $\hat{\sigma}_{ols}^2 = \frac{1}{T}\sum_{t=1}^{T} e_t^2$ where the e's are the OLS residuals. EViews actually uses a more sophisticated approach. Because the first-order conditions are nonlinear, they are solved using an iterative search procedure. In order to implement such a procedure, starting values for the parameters need to be specified. The OLS estimates of δ_0 and δ_1 from the mean equation are used as the starting values for these parameters, respectively. In the absence of GARCH effects, α_0 can be interpreted as the unconditional variance of the $\varepsilon's$. Thus, an appropriate starting value of α_0 is $\hat{\sigma}_{ols}^2$. For α_1 and β_1, arbitrarily select a small number (say, 0.05) for both as a starting value. The search procedure will iterate from these starting values and continue until a convergence criterion is satisfied. Hopefully, the resulting estimates will correspond to a global and not just a local maximum of the log-likelihood function.

Email: tutorcs@163.com
QQ: 749389476
https://tutorcs.com

4. Tests for ARCH\GARCH Effects

To see whether there are ARCH\GARCH effects evident in the data, first estimate the mean equation by OLS and save the residuals. Denote the OLS residuals from the mean equation as e_t. Consider the autocorrelations of the squared OLS residuals, that is, of e_t^2. If the autocorrelations for the squared residuals are large and exceed the Bartlet bands, that is an indication of the presence of ARCH\GARCH effects

in the data. Alternatively, one may use an LM test for ARCH\GARCH. Estimate the auxiliary regression

程序代写代做 CS编程辅导

$$e_t^2 = \gamma_0 + \gamma_1 e_{t-1}^2 + \ldots + \gamma_q e_{t-q}^2 + v_t$$

where the e's are [illegible] om the mean equation and v_t is an error term. Obtain the R^2 fro[illegible] e LM test statistic is

$$TR^2 \sim \chi_q^2$$

where T is number of OLS residuals. The null and alternative hypotheses are

$$H_0 : \gamma_i = 0 \text{ for all } i = 1, 2, \ldots, q.$$
$$H_1 : \gamma_i \neq 0 \text{ for at least one } i = 1, 2, \ldots, q.$$

WeChat: cstutorcs

Large values of TR^2 lead to a rejection of the null hypothesis of no ARCH\GARCH effects. Alternatively, an F-test for $\gamma_i = 0$ for all $i = 1, 2, \ldots, q$ could also be used.

Assignment Project Exam Help

5. Tests of Model Adequacy

Email: tutorcs@163.com

It can be shown that if $\varepsilon_t \mid \Omega_{t-1} \sim N(0, \sigma_t^2)$ then

$$\frac{\varepsilon_t}{\sigma_t} = v_t \sim iidN(0,1)$$

QQ: 749389476

This provides a means to check on the adequacy of the estimated ARCH\GARCH model. Standardize the residuals e_t by the conditional standard deviation from the fitted ARCH\GARCH model σ_t to get (e_t / σ_t). If the ARCH\GARCH model is adequate, then the standardized residuals should be uncorrelated and homoscedastic. Standard tests can be applied to the standardized residuals to see whether that is the case.

https://tutorcs.com

Finally, the standardized residuals should appear normally distributed. When the assumption of conditional normality does not hold, the ARCH\GARCH parameter estimates will still be consistent provided the mean and variance equations are correctly specified. However, the standard errors are no longer correct. In this case, we treat the log-likelihood function as being approximately correct but calculate robust standard errors. This approach is known as Quasi-Maximum Likelihood and the resulting standard errors are known as Bollerslev-Wooldridge standard errors. The Jarque-Bera test can be applied to the standardized residuals to test for normality.

6. An Application to the NYSE Composite Index

Figure 1 shows a graph of the percentage daily logarithmic change in the NYSE Composite Index (which is the percentage daily log return, denoted sr_t) over the period

January 3, 1995 to August 30, 2002, a total of 1,931 observations. Figure 2 shows a graph of the squared returns that is, s_i^2). Volatility clustering is apparent in this graph whereby large changes tend to be followed by large changes and small changes by small changes.

On the basis of the autocorrelation and partial autocorrelation function for returns (that is, for sr_t), it was decided to fit an MA(1) model for returns. The results are reported in Table 1 where it can be seen that the coefficient on the MA(1) term is statistically significant. An LM test for ARCH\GARCH effects is applied to the estimated residuals from the [illegible] The results are reported in Table 2.

In Table 2, the TR^2 statistic of 18.47 is highly significant with a p-value of 0.00. Thus, the null hypothesis of no ARCH\GARCH effects is emphatically rejected. Many of the lagged squared residuals are statistically significant indicating that volatility clustering is a fea

As a first varying volatility in the returns on the NYSE index, we fitted a odel to sr_t. The results are shown in Table 3. Here the model fc of as comprising a mean equation for sr_t, specified as an MA(1) proc uation for sr_t, specified as an ARCH(5) process. Both are estimate od of maximum likelihood. All the coefficients in the ARCH specifi that the conditional variance is always positive, and the coefficients on the lagged squared residuals sum to 0.731, a number less than one as required for a finite unconditional variance. The estimated coefficients on the lagged squared residuals are all statistically significant. This suggests that even higher-order ARCH models may be required. However, ARCH-type models with long lags are not parsimonious and it is usually preferable to estimate a GARCH(1,1) specification for the variance equation.

Durbin-Watson stat	2.074987	Prob(F-statistic)	0.627095

Table 4 shows the results of estimating an MA(1)-GARCH(1,1) model for returns (sr_t). The coefficient on the MA(1) term is statistically significant. In the GARCH specification, all the parameter estimates are statistically significant and positive. The ARCH coefficient (α_1) and the GARCH coefficient (β) sum to a value very near unity (0.996), with β ((0.887) larger then α_1 (0.109) as is commonly found in financial data.

Table 4: Estimati[illegible]H(1,1)

Table 5 shows the results of performing an LM test for remaining heteroscedasticity (that is, ARCH\GARCH effects) in the standardized MA(1)-GARCH(1,1) residuals. The TR^2 statistic of 3.87 is not statistically significant at conventional significance levels (it has a p-value of 0.57). Furthermore, in the auxiliary regression, none of the coefficients on the lagged squared standardized residuals are significant indicating that there is no remaining heteroscedasticity to be modeled.

Figure 3 presents a histogram of the standardized MA(1)-GARCH(1,1) residuals and associated summary statistics. The distribution appears symmetric and fat-tailed. The coefficient of kurtosis is quite high and the Jarque-Bera test clearly rejects normality. This suggests that the standard errors reported in Table 4 are not correct and that robust standard errors should be used instead. Table 6 reports estimates of the MA(1)-GARCH(1,1) model for returns with robust standard errors. Notice the coefficient estimates do not change just the standard errors. Nevertheless on the basis of the robust (Bollerslev-Wooldridge) standard errors there is no change in inference in this case.

Email: tutorcs@163.com
QQ: 749389476
https://tutorcs.com

Now we estimate the MA(1)-GARCH(1,1) model for returns using observations 1-1531, leaving 400 observations for use in an out-of-sample forecasting exercise. Specifically, the MA(1)-GARCH(1,1) model for returns is estimated over observations 1-1531 and used to generate a dynamic forecast of the conditional standard deviation for the out-of-sample observations 1532-1931. The results are shown in Figure 5. The forecast begins just following a reduction in volatility (that is, in the conditional standard deviation). The forecast is for a gradual increase in volatility. The long-run volatility forecast is the unconditional standard deviation of sr_t .Letting b_1 denote the MA(1) coefficient, the formula for the unconditional variance is

$$\begin{aligned}\mathrm{var}(sr_t) &= (1+b_1^2)\,\mathrm{var}(\varepsilon_t)\\ &= \frac{(1+b_1^2)\alpha_0}{1-(\alpha_1+\beta)} = \frac{(1+(0.1037)^2)0.0126}{1-(0.1099+0.8859)} = 3.0323\end{aligned}$$

Thus, $\sigma = 1.7413$ which is the value the forecast of the conditional standard deviation is approaching in Figure 5.
