Long-run relationships

程序代写代做 CS编程辅导

- Co-movement among time series

eg. US zero coupon bond rates: 3-month vs 9-month

<https://tutorcs.com>

(1946:12-1987:2, 483 monthly observations)

Both appear non-stationary but move together.

Long-run relationships

程序代写代做 CS编程辅导

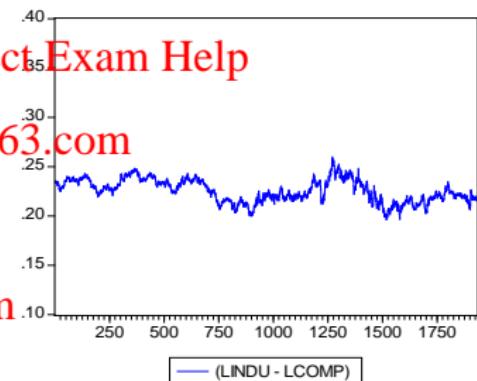

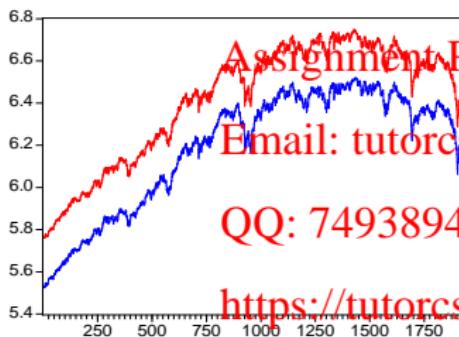

- Co-movement among time series

eg. US zero coupon bond 1-month vs 9-month

eg. NYSE log Composite & Industrial indices

Both are non-stationary but move together.

Long-run relationships

- Co-movement among time series

- Two (or more) time series **move together** over time and never depart for long.
- The time series are individually $I(1)$ and vary a great deal. But their **long-run relationship** appears stable over time.
- There must be a **common trend** that drives both time series.
- Important to exploit long-run relationships in finance eg. pairs-trading; rational bubbles; bi-listed stocks
- We introduce basic facts on modelling long-run relationships, mainly with **bi-variate** cases.

<https://tutorcs.com>

pairs=trading

程序代写代做 CS编程辅导

Pairs trading is a market-neutral trading strategy that matches a long position with a short position in a pair of highly correlated instruments such as two stocks, exchange-traded funds (ETFs), currencies, commodities or options. Pairs traders wait for weakness in the correlation and then go long the under-performer while simultaneously short selling the over-performer, closing the positions as the relationship reverts to statistical norms.

The spurious regression problem

- ▶ **General result:** a linear combination z_t of a set of variables x_{it} , with order $x_{it} \sim I(1)$, will have an order of integration equal to 1, if there exists a linear combination $\sum_{i=1}^k \alpha_i x_{it} \sim I(0)$
- ▶ Example: consider two series y_t and x_t , with

Assignment Project Exam Help

$y_t \sim I(1); x_t \sim I(1)$
Email: tutorcs@163.com

and a linear combination z_t thereof, i.e.

QQ: 749389476

$$z_t = \alpha_0 + \alpha_1 y_t + \alpha_2 x_t \sim I(0)$$

<https://tutorcs.com>

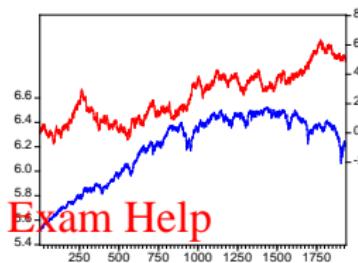

The spurious regression problem

- Example: NYSE Composite index vs Simulated RW

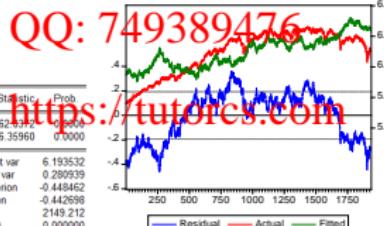

WeChat: cstutorcs

Examples of Spurious Regression

- Egyptian infant mortality rate (Y_t), 1971-1990, annual data, on gross aggregate income of American farmers (I_t) and total Honduran money supply (M_t)

$$\hat{Y}_t = 179.9 - 0.30I_t - 0.04M_t$$

(16.63) (-2.32) (-4.26)

Assignment Project Exam Help

$R^2 = 0.918; F = 95.17; DW = 0.475$

Email: tutorcs@163.com

- US export index (Y_t), 1960-1990, annual data, on Australian males life expectancy (X_t)

$$Y_t = 2945 + 45.80X_t$$

(16.70) (17.76)

$R^2 = 0.916; F = 315.2; DW = 0.360$

The spurious regression problem

$$\epsilon_t = \beta_1 + \beta_2 x_t + \epsilon_t$$

- The spurious regression problem is characterized by
 - Highly significant value for β_2
 - Fairly high R^2
- Reason: distribution of the conventional test statistics are very different from conventional case (stationary data)
 - OLS estimator does not converge in probability as $T \rightarrow \infty$
 - t -stats do not have well-defined asymptotic distributions
 - Estimated stdv strongly underestimates true stdv (b/c autocorrelation)
- Sign something is wrong:
 - Highly autocorrelated residuals

Implication

程序代写代做 CS编程辅导

The spurious regression problem implies that when regressing non-stationary variables, the estimation results should not be taken too seriously!!!

WeChat: cstutorcs

- Take first-differences of $I(1)$ variables (GLS correction for autocorrelation)

Assignment Project Exam Help

An important exception arises when the non-stationary series have a common stochastic trend: cointegration.

QQ: 749389476

- Don't take first differences

- specification error!
- advantage of $I(1)$ variables (superconsistency)

<https://tutorcs.com>

Definition cointegration

The k variables of the $\text{for } x_t = (x_{1t}, x_{2t}, \dots, x_{kt})'$ are said to be cointegrated of order **one**, denoted as $x_1 \sim CI(1)$ if

- ① All variables in x_t are integrated of the same order **one**, i.e. $x_{it} \sim I(1)$, for all i
- ② There exists at least one vector $\beta = (\beta_1, \beta_2, \dots, \beta_k)'$ of coefficients, called the **cointegrating vector**, such that the linear combination

$$x_t' \beta = (\beta_1 x_{1t} + \beta_2 x_{2t} + \dots + \beta_k x_{kt})$$

QQ: 749389476

is integrated of a order **zero**, i.e. $x_t \sim I(0)$

<https://tutorcs.com>

Example

程序代写代做 CS编程辅导

In practice, $x_t \sim CI(1)$ is common.

Consider for instance the time series, y_t and x_t , which are both $I(1)$.

If the residuals ϵ_t of the regression

$$y_t = \beta_1 + \beta_2 x_t + \epsilon_t$$

WeChat: cstutorcs

are $I(0)$, i.e. $\epsilon_t \sim I(0)$, then y_t and x_t are said to be cointegrated of order $CI(1)$ with cointegrating vector $\beta = (1, -\beta_1, -\beta_2)$.

Email: tutorcs@163.com
 $y_t - \beta_1 - \beta_2 x_t = \epsilon_t \sim I(0)$

QQ: 749389476

- eg. When $(9monthRate - 3monthRate)$ is stationary, they are cointegrated with cointegrating vector $\beta = [1, -1]$.
- eg. When $(logIndustrial - 0.98 logComposite)$ is stationary, they are cointegrated with cointegrating vector $\beta = [1, -0.98]$.

<https://tutorcs.com>

Cointegration & common trend

- Common trend

eg. A model of interest rates (Fisher equation)

- Short & long term interest rates (r_t^s, r_t^l) are directly influenced by the inflation π_t), subject to stationary shocks ($\epsilon_t^s, \epsilon_t^l$) :

WeChat: cstutorcs
Assignment Project Exam Help

- Both will be $I(1)$ when the π_t is $I(0)$.

Here π_t acts as the common trend that represents the trend

(non-stationary part) in both r_t^s and r_t^l .

- (r_t^s, r_t^l) are cointegrated with $\beta = [1, -1]'$ because

$$r_t^s - r_t^l = a^s - a^l + \epsilon_t^s - \epsilon_t^l \text{ is } I(0).$$

<https://tutorcs.com>

Economic Interpretation

If two (or more) series y_t and x_t are integrated of the same order, they can be combined to form an **equilibrium** relation

$$\beta_1 + \beta_2 x_t$$

then even though the series themselves are non-stationary they will nevertheless move closely together over time, i.e. they have a **common trend**, such that deviations from the equilibrium

Assignment Project Exam Help

$\epsilon_t = y_t - (\beta_1 + \beta_2 x_t)$
Email: tutorcs@163.com

are stationary.

QQ: 749389476

- The concept of cointegration indicates the existence of a long-run equilibrium to which an economic system converges over time and ϵ_t can be interpreted as the equilibrium error, i.e. the distance the system is away from the equilibrium at time t. As equilibrium errors should be temporary, ϵ_t should be stationary.

Https://tutorcs.com

Economic Interpretation

- The concept of spurious regression indicates that there is no long-run equilibrium relation between y_t and x_t as the error term ϵ_t is non-stationary, implying that deviations from the presumed relation between y_t and x_t are permanent such that this relation is not a long-run equilibrium relation.

QQ: 749389476

<https://tutorcs.com>

Econometric implication

- If non-stationary variables are cointegrated, regression analysis imparts meaningful information about the long-run relationship between the variables.

WeChat: cstutorcs

In fact, it can be shown that in this case, the OLS estimator $\hat{\beta}$ is even a **super consistent** estimator for β , i.e. $\hat{\beta}$ converges to β at a much faster rate than with conventional asymptotics (i.e. for stationary variables).

- If non-stationary variables are not cointegrated, regression results are not meaningful, i.e. spurious regression problem.

QQ: 749389476
<https://tutorcs.com>

Cointegration and Error-Correction Mechanisms

The existence of a long-run equilibrium relationship also has its implications for the short-run behaviour of the $I(1)$ variables

WeChat: cstutorcs

- The **Granger representation theorem** states that if a set of variables is cointegrated, there has to be a mechanism that drives the variables back to their long-run equilibrium relationship after the equilibrium has been disturbed by a shock.

Assignment Project Exam Help

Email: tutors@163.com

QQ: 749389476

- This mechanism is called an **error-correction model**

<https://tutorcs.com>

Example of an error-correction model

Consider two variables which are cointegrated with cointegrating vector β

$y_t = \beta_1 + \beta_2 x_{t-1} + \mu_t$

A simple error-correction model (ECM) is given by

$$\Delta y_t = \gamma_1 \Delta x_t - \alpha(y_{t-1} - \beta_1 - \beta_2 x_{t-1}) + \mu_t \quad (1)$$

$$= \gamma_1 \Delta x_t - \alpha \epsilon_{t-1} + \mu_t \quad (2)$$

Assignment Project Exam Help

The ECM incorporates both **short-run** and **long-run** effects

- The long-run equilibrium is obtained by imposing the 'no change' condition $\Delta y_t = \Delta x_t = \mu_t = 0$ and solve for y_t

QQ: 749389476

$y_t = \beta_1 + \beta_2 x_t$
<https://tutorcs.com>

Thus, the long-run impact of x_t on y_t is given by β_2 .

- The contemporaneous impact of x_t on y_t is given by γ_1 .

Error correction mechanism

- ▶ The term $-\alpha\epsilon_{t-1}$ is called the error-correction mechanism. If y_t and x_t are cointegrated, Granger representation theorem implies that $\alpha > 0$.

- ▶ When y_t is below its equilibrium value implied by x_t , $\epsilon_t < 0$ such that y_t increases back to the equilibrium
- ▶ When y_t is above its equilibrium value implied by x_t , $\epsilon_t > 0$ such that y_t decreases back to the equilibrium

WeChat: cstutors

Assignment Project Exam Help

Note that α measures the **speed of adjustment** towards the equilibrium. The smaller α (i.e. the closer to zero), the lower this speed of adjustment.

- When y_t and x_t are cointegrated, ϵ_t is the deviation from their long-run equilibrium.
- y_{t+1} and x_{t+1} must move toward eliminating the deviation, or correcting the cointegration error ϵ_t .
- Hence, ϵ_t is useful for predicting Δy_{t+1} and Δx_{t+1} and the models for Δy_{t+1} and Δx_{t+1} should include ϵ_t as an explanatory variable.

QQ: 749389476

<https://tutors.com>

程序代写代做 CS编程辅导

Vector Error correction VEC

- Vector error correction (VEC) model:

$$\epsilon_{t-1} = y_{t-1} - \beta_0 - \beta_1 x_{t-1} \quad (3)$$

$$\Delta x_t = c_1 + \alpha_1 \epsilon_{t-1} + \phi_{11} \Delta x_{t-1} + \phi_{12} \Delta y_{t-1} + u_{1t} \quad (4)$$

$$\Delta y_t = c_2 + \alpha_2 \epsilon_{t-1} + \phi_{21} \Delta x_{t-1} + \phi_{22} \Delta y_{t-1} + u_{2t} \quad (5)$$

- Eg, when $\alpha_1 = 0$, the adjustment toward equilibrium is all done by y_t and the common trend is x_t .

QQ: 749389476

Call α_1 and α_2 adjustment coefficients.

What happens when both α_1 and α_2 are zero?

Price discovery in parallel markets

How information is incorporated into prices?

- Examples (usually commodity price series)

- Bi-listed stock: which market sets the price?
- Spot & futures prices: does spot follows futures?

WeChat: cstutorcs

- For two log prices, y_t and x_t , on the same asset, the rule-of-one-price dictates that $\epsilon_t = y_t - x_t$ can only fluctuate around zero.

Email: tutorcs@163.com

- Hence, y_t and x_t are cointegrated with $[1, -1]$ being the cointegrating vector. The error correction model is applicable.
- The relative magnitudes of α_1 and α_2 can tell us to what extent x_t acts as price setter, $s_x = \frac{|\alpha_1|}{|\alpha_1| + |\alpha_2|}$

QQ: 740389476

<https://tutorcs.com>

Example: Price discovery in parallel markets

eg. SP500 spot & futures
 (20100104-20120101) (days.)

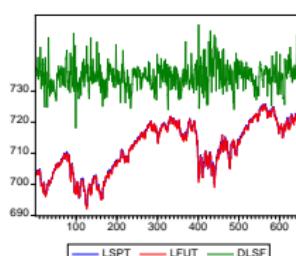

The adjustment coefficients:

α_{futures} is insignificant (t-stat = 0.46)

α_{spot} is significant (t-stat = -2.34).

Futures appears to be the price-setter!

US acts as the common trend.

Properties of OLS : Super consistency

Consider two time series x_t and y_t which are both $I(1)$. Estimating the static equation

$$y_t = \beta_1 + \beta_2 x_t + \epsilon_t$$

using OLS yields **super consistent** estimates of the long-run parameters β_1 and β_2 when ϵ_t is $I(0)$.

- ▶ Super consistency means that the OLS estimator converges to the true population parameters at a much faster rate than with stationary variables
- ▶ This result arises as OLS picks the coefficients $\hat{\beta}$ such that the variance of the estimated residuals $\hat{\epsilon}_t$ is as small as possible. As setting $\hat{\beta} \neq \beta$ implies that $\epsilon_t \sim I(1)$ such that its variance becomes infinitely large when $T \rightarrow \infty$, OLS is very efficient in picking the correct β
- ▶ The super consistency property of the OLS estimator implies that in estimating the long-run relation between cointegrated variables, dynamics and endogeneity issues can be ignored asymptotically

WeChat: cstutorcs

Assignment Project Exam Help

Email: tutorcs@163.com

QQ: 749389476

<https://tutorcs.com>

Properties of OLS : 桨序代写代做CS编程辅导

- If two I(1) series y_t and x_t are cointegrated, they may be fitted in the $y_t = \beta_0 + \beta_1 x_t + \varepsilon_t$ regression

$$y_t = \beta_0 + \beta_1 x_t + \varepsilon_t, \quad \varepsilon_t \text{ being stationary}$$

WeChat: cstutorcs
where $[1, -\beta_1]$ is the cointegrating vector.

- As long as ε_t is stationary, the OLS estimator of β_1 is consistent, but generally has a non-standard asymptotic distribution.
- To make valid inference about β_1 , the “dynamic” OLS estimator of β_1 from <https://tutorcs.com>

$$y_t = \beta_0 + \beta_1 x_t + \sum_{j=-q}^q \psi_j \Delta x_{t-j} + \varepsilon_t .$$

Properties of OLS : Super consistency

- The addition of leads and lags removes the deleterious effects that short-run dynamics of the equilibrium process ϵ_t have on the estimate of the cointegrating vector
- The DOLS estimator is consistent, asymptotically normally distributed, and efficient.
- Asymptotically valid standard errors for the individual elements of the estimated cointegration vector are given by their corresponding HAC (e.g., Newey-West) standard errors.

<https://tutorcs.com>

Testing for cointegration

Consider two time series y_t and x_t .

Suppose we want to estimate the following equation:

$$y_t = \beta_1 + \beta_2 x_t + \epsilon_t$$

Prior to estimation, test the variables for their order of integration

Assignment Project Exam Help

- ① If both are $I(0)$: standard regression analysis is valid
- ② If they are integrated of a different order, e.g. y_t is $I(1)$ and x_t is $I(0)$: there can be no (long-run) relation between these two variables
- ③ If both are $I(1)$: use cointegration analysis

Note however that there is almost never certainty about the true order of integration

<https://tutorcs.com>

The Engle-Granger two-step approach

A popular methodology to test for cointegration and to analyse cointegrating relationships is the so-called Engle-Granger two-step approach:

WeChat: cstutors
Assignment Project Exam Help

- ① Estimate the static model and test for cointegration
Email: tutorcs@163.com
- ② Estimate an ECM to analyse the short-run dynamics

QQ: 749389476

<https://tutorcs.com>

The Engle-Granger two-step approach

Step 1: estimate model and test for cointegration

Estimate the model using OLS. Two cases can be distinguished

1. The regression results are spurious if $\varepsilon_t \sim I(1)$
2. OLS is super consistent if $\varepsilon_t \sim I(0)$

WeChat: cstutorcs

Assignment Project Exam Help

Email: tutorcs@163.com

After estimating a model including non-stationary variables, it is therefore very important to test the order of integration of the estimated residuals $\hat{\varepsilon}_t$. We consider two alternative tests:

QQ: 749389476

1. The cointegrating regression Durbin-Watson (CRDW) test
2. ADF cointegration test

The Engle-Granger two-step approach

1. Cointegrating

Tests whether the residuals $\hat{\varepsilon}_t$ are generated by a unit root process:

WeChat: $\hat{\varepsilon}_t \sim \hat{\varepsilon}_{t-1} + v_t$

against the alternative that $\hat{\varepsilon}_t$ is generated by a stationary AR(1) process:

Email: tutorcs@163.com

$\hat{\varepsilon}_t = \rho \hat{\varepsilon}_{t-1} + v_t$ with $|\rho| < 1$

using the Durbin-Watson (DW) statistic.
<https://tutorcs.com>

As $DW \approx 2(1 - \rho)$ this test boils down to testing whether DW is significantly larger than zero.

The Engle-Granger two-step approach

- ▶ Formally:

$$H_0 : \hat{\varepsilon}_t \sim I(1) \text{ cointegrated} \rightarrow \rho = 1 \text{ or } d = 0$$

$$H_1 : \hat{\varepsilon}_t \sim I(0) \text{ cointegrated} \rightarrow \rho < 1 \text{ or } d > 0$$

- ▶ The 5% critical values for the CRDW test are given by

Number of variables (incl. y_t)	Number of observations 50	100	250
2	0.72	0.38	0.20
3	0.59	0.48	0.25

- ▶ Drawback: the CRDW test is only valid when ε_t follows an AR(1) process as the DW statistic only checks for an AR(1) pattern in the data.

The Engle-Granger two-step approach

2. ADF cointegration

Tests for a unit root
standard DF specification

estimated residuals using the

$$\Delta \hat{\varepsilon}_t = \gamma \hat{\varepsilon}_{t-1} + \sum_{i=1}^{p-1} \alpha_i \Delta \hat{\varepsilon}_{t-i} + \omega_t$$

with $H_0 : \gamma = 0 \rightarrow$ no cointegration

Assignment Project Exam Help

Important notes:

Email: tutorcs@163.com

- Deterministic components (i.e. intercept and trend) can be included either in the cointegrating regression or in the ADF test (but not in both)
- The standard DF critical values are not valid! Reason: the OLS estimator 'picks' such that the residuals $\hat{\varepsilon}_t$ have the lowest possible variance, i.e. making the residuals appear as stationary as possible even if there is no cointegration (i.e. ε_t is non-stationary).

<https://tutorcs.com>

The Engle-Granger two-step approach

Step 2: Estimate an ECM to analyse the short-run dynamics

Upon finding cointegration, estimate a ECM

$$A(L) \Delta y_t = \delta + B(L) \Delta x_t + \alpha \hat{\varepsilon}_{t-1} + C(L) u_t$$

where $\hat{\varepsilon}_{t-1} = y_{t-1} - \hat{\beta}_1 - \hat{\beta}_2 x_{t-1}$

Since all variables are $I(0)$, this can be done using OLS and statistical inference using standard t - and F -tests is possible.

Example: consumption, income and wealth in the US

- ▶ All data in natural log form, 1951:Q4-2005:Q4.
- ▶ ADF tests show that consumption is I(1)
 - ▶ Unit root in first differences is rejected
 - ▶ Unit root in levels is not rejected
- ▶ The null hypothesis of no cointegration can be rejected at the 5% level of significance
 - ▶ The CRDW equals 0.1, which is just above the 5% critical value of ≈ 0.30 .
 - ▶ The ADF test on the residuals of the static regression equals -4.19 , which is below the 5% critical value -3.78 ($= -3.7429 - 8.352/217 - 13.41/217^2$).
- ▶ The error-correction term is significant and shows that consumption is only slowly converging to the long-run equilibrium implied by income and wealth, i.e. every quarter 5.7% of the equilibrium gap is closed.
